1 GENERAL DESCRIPTION

SSD1320 is a single-chip CMOS OLED/PLED driver with controller for organic/polymer light emitting diode dot-matrix graphic display. It consists of 160 segments and 160 commons. This IC is designed for Common Cathode type OLED/PLED panel.

SSD1320 embeds with contrast control, display RAM and oscillator, which reduce the number of external components and power consumption. It has 160 x 160 x 4 bits Graphic Display Data RAM (GDDRAM), and supports 256-step contrast. Data/Commands are sent from generic MCU through the hardware selectable 6800/8080 series compatible Parallel Interface, I2C interface or Serial Peripheral Interface. SSD1320 is designed to support high brightness panel, with maximum source current reaching 600μA, making it suitable for many compact portable applications which requires sunlight readability, such as wearable electronics etc.

2 FEATURES

- Resolution: 160 x 160 dot matrix panel
- Power supply
  - $V_{DD} = 1.65V – 3.5V$ (for IC logic)
  - $V_{CC} = 8.0V – 18.0V$ (for Panel driving)
- Segment maximum source current: 600μA
- Common maximum sink current: 96mA
- Embedded 160 x 160 x 4-bit SRAM display buffer
- Pin selectable MCU Interfaces:
  - 8 bits 6800/8080-series parallel Interface
  - 3/4 wire Serial Peripheral Interface
  - I²C Interface
- Screen saving continuous scrolling function in both horizontal and vertical direction
- Screen saving infinite content scrolling function
- Internal or external IREF selection
- RAM write synchronization signal
- Programmable Frame Rate and Multiplexing Ratio
- Row Re-mapping and Column Re-mapping
- Power On Reset (POR)
- On-Chip Oscillator
- Power Save Mode
- Chip layout for COG, COF
- Wide range of operating temperature: -40°C to 85°C

</tbody>
</table>
| E (RD#)    | I        | This pin is MCU interface input.  
When 6800 interface mode is selected, this pin will be used as the Enable (E) signal. Read/write operation is initiated when this pin is pulled HIGH and the chip is selected.  
When 8080 interface mode is selected, this pin receives the Read (RD#) signal. Read operation is initiated when this pin is pulled LOW and the chip is selected.  
When serial or I^2C interface is selected, this pin must be connected to V_{SS}. |
| D[7:0]     | I/O      | These pins are bi-directional data bus connecting to the MCU data bus. Unused pins are recommended to tie LOW.  
When serial interface mode is selected, D2, D1 should be tied together as the serial data input: SDIN, and D0 will be the serial clock input: SCLK.  
When I^2C mode is selected, D2, D1 should be tied together and serve as SDA_{out}, SDA_{in} in application and D0 is the serial clock input, SCL. |
| FR         | O        | This pin outputs RAM write synchronization signal. Proper timing between MCU data writing and frame display timing can be achieved to prevent tearing effect. It should be kept NC if it is not used. |
| T0         | I/O      | This is a reserved pin. It should be kept NC.                                                                                                                                                              |
| T1         | I/O      | This is a reserved pin. It should be kept NC.                                                                                                                                                              |
| SEG0 ~ SEG159 | O    | These pins provide the OLED segment driving signals. These pins are V_{SS} state when display is OFF.                                                                                                    |
| COM0 ~ COM159 | O    | These pins provide the Common switch signals to the OLED panel. These pins are in high impedance state when display is OFF.                                                                               |
| TR[15:0]   | -        | Reserved pin and is recommended to keep it float.                                                                                                                                                         |
| NC         | -        | This is dummy pin. It should be kept NC.                                                                                                                                                                  |
6 FUNCTIONAL BLOCK DESCRIPTIONS

6.1 MCU Interface selection
SSD1320 MCU interface consist of 8 data pins and 5 control pins. The pin assignment at different interface
mode is summarized in Table 6-1. Different MCU mode can be set by hardware selection on BS[2:0] pins
(please refer to Table 5-2 for BS[2:0] setting).

<table>
<thead>

</tr>
</tbody>
</table>

When serial interface mode is selected, D0 will be the serial clock input: SCLK; D1 and D2 should be tied
together as the serial data input: SDIN.

6.1.1 MCU Parallel 6800-series Interface
The parallel interface consists of 8 bi-directional data pins (D[7:0]), R/W#, D/C#, E and CS#.

A LOW in R/W# indicates WRITE operation and HIGH in R/W# indicates READ operation.
A LOW in D/C# indicates COMMAND read/write and HIGH in D/C# indicates DATA read/write.
The E input serves as data latch signal while CS# is LOW. Data is latched at the falling edge of E signal.

<table>

</tbody>
</table>

Note
(1) ↓ stands for falling edge of signal
H stands for HIGH in signal
L stands for LOW in signal

In order to match the operating frequency of display RAM with that of the microprocessor, some pipeline
processing is internally performed which requires the insertion of a dummy read before the first actual display
data read. This is shown in Figure 6-1.
6.1.2 MCUs Parallel 8080-Series Interface

The parallel interface consists of 8 bi-directional data pins (D[7:0]), RD#, WR#, D/C# and CS#.

A LOW in D/C# indicates COMMAND read/write and HIGH in D/C# indicates DATA read/write.

A rising edge of RD# input serves as a data READ latch signal while CS# is kept LOW.

A rising edge of WR# input serves as a data/command WRITE latch signal while CS# is kept LOW.

(2) H stands for HIGH in signal
(3) L stands for LOW in signal

In order to match the operating frequency of display RAM with that of the microprocessor, some pipeline processing is internally performed which requires the insertion of a dummy read before the first actual display data read. This is shown in Figure 6-4.

Figure 6-4: Display data read back procedure - insertion of dummy read

6.1.3 MCU Serial Interface (4-wire SPI)

The 4-wire serial interface consists of serial clock: SCLK, serial data: SDIN, D/C#, CS#. In 4-wire SPI mode, D0 acts as SCLK, D1 and D2 are tied together to act as SDIN. For the unused data pins from D3 to D7, E(RD#) and R/W#(WR#) can be connected to an external ground.

Table 6-4: Control pins of 4-wire Serial interface

Note
(1) H stands for HIGH in signal
(2) L stands for LOW in signal
(3) ↑ stands for rising edge of signal

SDIN is shifted into an 8-bit shift register on every rising edge of SCLK in the order of D7, D6, ..., D0. D/C# is sampled on every eighth clock and D/C# should be kept stable throughout eight clock period. The data byte in the shift register is written to the Graphic Display Data RAM (GDDRAM) or command register in the same clock.

Under serial mode, only write operations are allowed.
6.1.4 MCU Serial Interface (3-wire SPI)
The 3-wire serial interface consists of serial clock SCLK, serial data SDIN and CS#.
In 3-wire SPI mode, D0 acts as SCLK, D1 and D2 are tied together to act as SDIN. For the unused data pins from D3 to D7, R/W# (WR#), E(RD#) and D/C# can be connected to an external ground.

The operation is similar to 4-wire serial interface while D/C# pin is not used. There are altogether 9-bits will be shifted into the shift register on every ninth clock in sequence: D/C# bit, D7 to D0 bit. The D/C# bit (first bit of the sequential data) will determine the following data byte in the shift register is written to the Display Data RAM (D/C# bit = 1) or the command register (D/C# bit = 0).

Under serial mode, only write operations are allowed.

1. L stands for LOW in signal
2. ↑ stands for rising edge of signal

Under serial mode, only write operations are allowed.
6.1.5 MCU I2C Interface

The I2C communication interface consists of slave address bit SA0, I2C-bus data signal SDA (SDA\textsubscript{OUT}/D\textsubscript{2} for output and SDA\textsubscript{IN}/D\textsubscript{1} for input) and I2C-bus clock signal SCL (D\textsubscript{0}). Both the data and clock signals must be connected to pull-up resistors. RES# is used for the initialization of device.

a) Slave address bit (SA0)
SSD1320 has to recognize the slave address before transmitting or receiving any information by the I2C-bus. The device will respond to the slave address following by the slave address bit (“SA0” bit) and the read/write select bit (“R/W#” bit) with the following byte format,

\[
\begin{array}{cccccccc}
\text{b7} & \text{b6} & \text{b5} & \text{b4} & \text{b3} & \text{b2} & \text{b1} & \text{b0} \\
0 & 1 & 1 & 1 & 1 & 0 & \text{SA0} & \text{R/W#}
\end{array}
\]

“SA0” bit provides an extension bit for the slave address. Either “0111100” or “0111101”, can be selected as the slave address of SSD1320. D/C# pin acts as SA0 for slave address selection.

“R/W#” bit is used to determine the operation mode of the I2C-bus interface. R/W#=1, it is in read mode. R/W#=0, it is in write mode.

b) I2C-bus data signal (SDA)
SDA acts as a communication channel between the transmitter and the receiver. The data and the acknowledgement are sent through the SDA.

It should be noticed that the ITO track resistance and the pulled-up resistance at “SDA” pin becomes a voltage potential divider. As a result, the acknowledgement would not be possible to attain a valid logic 0 level in “SDA”.

“SDA\textsubscript{IN}” and “SDA\textsubscript{OUT}” are tied together and serve as SDA. The “SDA\textsubscript{IN}” pin must be connected to act as SDA. The “SDA\textsubscript{OUT}” pin may be disconnected. When “SDA\textsubscript{OUT}” pin is disconnected, the acknowledgement signal will be ignored in the I2C-bus.

c) I2C-bus clock signal (SCL)
The transmission of information in the I2C-bus is following a clock signal, SCL. Each transmission of data bit is taken place during a single clock period of SCL.
6.1.5.1 I²C-bus Write data
The I²C-bus interface gives access to write data and command into the device. Please refer to Figure 6-7 for the write mode of I²C-bus in chronological order.

![Figure 6-7: I²C-bus data format](image)

6.1.5.2 Write mode for I²C

1) The master device initiates the data communication by a start condition. The definition of the start condition is shown in Figure 6-8. The start condition is established by pulling the SDA from HIGH to LOW while the SCL stays HIGH.

2) The slave address is following the start condition for recognition use. For the SSD1320, the slave address is either “b0111100” or “b0111101” by changing the SA0 to LOW or HIGH (D/C pin acts as SA0).

3) The write mode is established by setting the R/W# bit to logic “0”.

4) An acknowledgement signal will be generated after receiving one byte of data, including the slave address and the R/W# bit. Please refer to the Figure 6-9: Definition of the acknowledgement condition for the graphical representation of the acknowledge signal. The acknowledge bit is defined as the SDA line is pulled down during the HIGH period of the acknowledgement related clock pulse.

5) After the transmission of the slave address, either the control byte or the data byte may be sent across the SDA. A control byte mainly consists of Co and D/C# bits following by six “0” ‘s.
   a. If the Co bit is set as logic “0”, the transmission of the following information will contain data bytes only.
   b. The D/C# bit determines the next data byte is acted as a command or a data. If the D/C# bit is set to logic “0”, it defines the following data byte as a command. If the D/C# bit is set to logic “1”, it defines the following data byte as a data which will be stored at the GDDR. The GDDR column address pointer will be increased by one automatically after each data write.

6) Acknowledge bit will be generated after receiving each control byte or data byte.

7) The write mode will be finished when a stop condition is applied. The stop condition is also defined in Figure 6-8. The stop condition is established by pulling the “SDA in” from LOW to HIGH while the “SCL” stays HIGH.

---

Solomon Systech
May 2017  P 16/39  Rev 1.0  SSD1320
Figure 6-8: Definition of the Start and Stop Condition

Figure 6-9: Definition of the acknowledgement condition

Please be noted that the transmission of the data bit has some limitations.
1. The data bit, which is transmitted during each SCL pulse, must keep at a stable state within the “HIGH” period of the clock pulse. Please refer to the Figure 6-10 for graphical representations. Except in start or stop conditions, the data line can be switched only when the SCL is LOW.
2. Both the data line (SDA) and the clock line (SCL) should be pulled up by external resistors.

Figure 6-10: Definition of the data transfer condition
6.2 Command Decoder

This module determines whether the input data is interpreted as data or command. Data is interpreted based upon the input of the D/C# pin.

If D/C# pin is HIGH, D[7:0] is interpreted as display data written to Graphic Display Data RAM (GDDRAM). If it is LOW, the input at D[7:0] is interpreted as a command. Then data input will be decoded and written to the corresponding command register.

6.3 Oscillator Circuit and Display Time Generator

This module is an on-chip LOW power RC oscillator circuitry. The operation clock (CLK) can be generated either from internal oscillator or external source CL pin. This selection is done by CLS pin. If CLS pin is pulled HIGH, internal oscillator is chosen and CL should be connected to VSS. Pulling CLS pin LOW disables internal oscillator and external clock must be connected to CL pins for proper operation. When the internal oscillator is selected, its output frequency Fosc can be changed by command D5h A[7:4].

The display clock (DCLK) for the Display Timing Generator is derived from CLK. The division factor “D” can be programmed from 1 to 256 by command D5h

\[
\text{DCLK} = \frac{F_{\text{OSC}}}{D}
\]

The frame frequency of display is determined by the following formula.

\[
F_{\text{FRM}} = \frac{F_{\text{OSC}}}{D \times K \times \text{No. of Mux}}
\]

where
- D stands for clock divide ratio. It is set by command D5h A[3:0]. The divide ratio has the range from 1 to 256.
- K is the number of display clocks per row. The value is derived by
  \[ K = \text{Phase 1 period} + \text{Phase 2 period} + K_0 \]
  \[ = 7 + 2 + 66 = 75 \text{ at power on reset (that is } K_0 \text{ is a constant that equals to 66)} \]
  Please refer to Section 6.6 for the details of the “Phase”.
- Number of multiplex ratio is set by command A8h. The power on reset value is 159 (i.e. 160MUX).
- \( F_{\text{OSC}} \) is the oscillator frequency. It can be changed by command D5h A[7:4]. The higher the register setting results in higher frequency.
6.4 FR synchronization
FR synchronization signal can be used to prevent tearing effect.

The starting time to write a new image to OLED driver is depended on the MCU writing speed. If MCU can finish writing a frame image within one frame period, it is classified as fast write MCU. For MCU needs longer writing time to complete (more than one frame but within two frames), it is a slow write one.

**For fast write MCU:** MCU should start to write new frame of ram data just after rising edge of FR pulse and should be finished well before the rising edge of the next FR pulse.

**For slow write MCU:** MCU should start to write new frame ram data after the falling edge of the 1st FR pulse and must be finished before the rising edge of the 3rd FR pulse.

6.5 Reset Circuit
When RES# input is LOW, the chip is initialized with the following status:
1. Display is OFF
2. 160 x 160 Display Mode
3. Normal segment and display data column address and row address mapping (SEG0 mapped to address 00h and COM0 mapped to address 00h)
4. Shift register data clear in serial interface
5. Display start line is set at display RAM address 0
6. Column address counter is set at 0
7. Normal scan direction of the COM outputs
8. Contrast control register is set at 7Fh
9. Normal display mode (Equivalent to A4h command)
6.6 Segment Drivers/Common Drivers

Segment drivers have 160 current sources to drive OLED panel. The driving current can be adjusted up to 600uA with 8 bits, 256 steps by contrast setting command (81h). Common drivers generate voltage scanning pulses. The block diagrams and waveforms of the segment and common driver are shown as follow.

**Figure 6-12: Segment and Common Driver Block Diagram**

The commons are scanned sequentially, row by row. If a row is not selected, all the pixels on the row are in reverse bias by driving those commons to voltage $V_{COMH}$ as shown in Figure 6-13.

In the scanned row, the pixels on the row will be turned ON or OFF by sending the corresponding data signal to the segment pins.

There are four phases to driving an OLED a pixel. In phase 1, the pixel is reset by the segment driver to \( V_{\text{LSS}} \) in order to discharge the previous data charge stored in the parasitic capacitance along the segment electrode. The period of phase 1 can be programmed by command D9h A[3:0]. An OLED panel with larger capacitance requires a longer period for discharging.

In phase 2, first pre-charge is performed. The pixel is driven to attain the corresponding voltage level \( V_P \) from \( V_{\text{LSS}} \). The amplitude of \( V_P \) can be programmed by the command BCh. The period of phase 2 can be programmed by command D9h A[7:4]. If the capacitance value of the pixel of OLED panel is larger, a longer period is required to charge up the capacitor to reach the desired voltage.

In phase 3, the OLED pixel is driven to the targeted driving voltage through second pre-charge. The second pre-charge can control the speed of the charging process. The period of phase 3 can be programmed by command DCh.

Last phase (phase 4) is current drive stage. The current source in the segment driver delivers constant current to the pixel. The driver IC employs PWM (Pulse Width Modulation) method to control the gray scale of each pixel individually. The gray scale can be programmed into different Gamma settings by command BEh/BFh. The bigger gamma setting (the wider pulse widths) in the current drive stage results in brighter pixels and vice versa. This is shown in the following figure.

![Figure 6-14: Gray Scale Control by PWM in Segment](image)

After finishing phase 4, the driver IC will go back to phase 1 to display the next row image data. This four-step cycle is run continuously to refresh image display on OLED panel.

The length of phase 4 is defined by command BEh/BFh. In the table, the gray scale is defined in incremental way, with reference to the length of previous table entry.
6.7 Graphic Display Data RAM (GDDRAM)

The GDDRAM is a bit mapped static RAM holding the bit pattern to be displayed. The size of the RAM is 160x160x4 bits. For mechanical flexibility, re-mapping on both Segment and Common outputs can be selected by software. The GDDRAM address maps in Table 6-6 to Table 6-10 show some examples to re-map the GDDRAM. In the following tables, the lower nibble and higher nibble of D0, D1, D2 … D12797, D12798, D12799 represent the 160x160 data bytes in the GDDRAM.

These are the commands for Re-map setting:

Table 6-6 shows the GDDRAM map under the following condition:
- Command Setting:
  - Disable Column Address Re-map
  - Horizontal Address Increment
  - Disable COM Re-map
  - Disable Portrait Mode
- Display Start Line=00h
- Data byte sequence: D0, D1, D2 … D12799

6.8 SEG/COM Driving block

This block is used to derive the incoming power sources into the different levels of internal use voltage and current.

- $V_{CC}$ is the most positive voltage supply.
- $V_{COMH}$ is the Common deselected level. It is internally regulated.
- $V_{LSS}$ is the ground path of the analog and panel current.
- $I_{REF}$ is a reference current source for segment current drivers $I_{SEG}$. The relationship between reference current and segment current of a color is:

$$I_{SEG} = \frac{\text{Contrast}}{4} \times I_{REF}$$

in which the contrast (1~255) is set by Set Contrast command 81h

When internal $I_{REF}$ is used, the $I_{REF}$ pin should be kept NC.

Bit A[4] of command ADh is used to select external or internal $I_{REF}$:

- A[4] = ‘0’ Select external $I_{REF}$ [Reset]
- A[4] = ‘1’ Enable internal $I_{REF}$ during display ON

When external $I_{REF}$ is used, the magnitude of $I_{REF}$ is controlled by the value of resistor, which is connected between $I_{REF}$ pin and $V_{SS}$ as shown in Figure 6-15:

$$\text{IREF Current Setting by Resistor Value}$$

$$\text{Figure 6-15: } I_{REF} \text{ Current Setting by Resistor Value}$$

Since the voltage at $I_{REF}$ pin is $V_{CC} – 2V$, the value of resistor R1 can be found as below:

For $I_{REF} = 10\mu A$, $V_{CC} = 12V$:

$$R1 = \frac{(\text{Voltage at } I_{REF} - V_{SS})}{I_{REF}}$$
$$\approx \frac{(12 - 2)}{10\mu A}$$
$$= 1M\Omega$$
6.9 Power ON and OFF sequence

The following figures illustrate the recommended power ON and power OFF sequence of SSD1320.

**Power ON sequence:**
1. Power ON VDD
2. After VDD become stable, wait at least 20ms (t₀), set RES# pin LOW (logic low) for at least 3us (t₁) and then HIGH (logic high).
3. After set RES# pin LOW (logic low), wait for at least 3us (t₂). Then Power ON VCC
4. After VCC become stable, send command AFh for display ON. SEG/COM will be ON after 100ms (t_AF).

---

**Figure 6-16: Power ON Sequence**

---

**Power OFF sequence:**
1. Send command AEh for display OFF.
2. Power OFF VCC
3. Power OFF VDD after t_OFF, (where Minimum t_OFF = 0ms, typical t_OFF = 100ms)

---

**Figure 6-17: Power OFF Sequence**

---

**Note:**

1. V_CC should be kept float (i.e. disable) when it is OFF.
2. Power Pins (V_DD, V_CC) can never be pulled to ground under any circumstance.
3. The register values are reset after t₁.
4. V_DD should not be Power OFF before V_CC Power OFF.

Figure 9-5: I²C interface Timing characteristics
10 APPLICATION EXAMPLE

Figure 10-1: Application Example of SSD1320Z

The configuration for 4-wire SPI interface mode is shown in the following diagram:
\( V_{DD}=1.8V, V_{CC}=15V, I_{REF}=10\mu A \)

The display panel is 160 x 160 pixels.

SSD1320Z

- **Pin connected to MCU interface:** D[2:0], RES#, D/C#, CS#
- **Pin internally connected to \( V_{LSS} \):** VSL
- **Pin internally connected to \( V_{SS} \) (or \( V_{LL} \)):** D[7:3], BS[2:0], E, R/W#, CL, BGND
- **Pin internally connected to \( V_{DD} \) (or \( V_{LL} \)):** CLS
- **\( V_{BE} \), \( V_{F} \), FR, T0, T1, TR[15:0],** should be left open.

- C1, C2: 2.2uF \(^{(1)}\)
- C3: 1.0uF \(^{(1)}\) place close to IC \( V_{DD} \) and \( V_{SS} \) pins on PCB

Voltage at \( I_{REF} = V_{CC} - 2V \). For \( V_{CC} = 15V, I_{REF} = 10\mu A \):

\[
R_1 = \frac{(V_{CC} - V_{SS})}{I_{REF}} \\
\approx \frac{(15-2)V}{10\mu A} \\
\approx 13M\Omega
\]

**Note**

\(^{(1)}\) The capacitor value is recommended value. Select appropriate value against module application.
\(^{(2)}\) Die gold bump face down.
\(^{(3)}\) All \( V_{LSS} \) pads of the IC are recommended to be connected together to form a larger area of GND.
\(^{(4)}\) \( V_{LSS} \) and \( V_{SS} \) are not recommended to be connected on the ITO routing, but connected together in the PCB level at one common ground point for better grounding and noise insulation.
The product(s) listed in this datasheet comply with Directive 2011/65/EU of the European Parliament and of the council of 8 June 2011 on the restriction of the use of certain hazardous substances in electrical and electronic equipment and People’s Republic of China Electronic Industry Standard GB/T 26572-2011 “Requirements for concentration limits for certain hazardous substances in electronic information products (电子电器产品中限用物质的限用要求)”. Hazardous Substances test report is available upon request.
